In the quest for development and prosperity human civilization has reached a crossroad where it is uncertain at finding the future course of action. Mother Earth, one of the eight planets in the Solar System, is continuously fouled by various anthropogenic activities, the main impact being caused by greenhouse gases.

After carbon dioxide (CO₂) the most injurious greenhouse gas is methane. In Earth's atmosphere its concentration is gradually increasing day by day as fuel methane is gaining popularity. From different sources methane gas is being emitted/released and creating a problem for the environment.
